ABSTRACT

Diabetes mellitus is a serious public health problem, S. aureus is the most common bacteria isolated from ulceration of diabetic patients, and increase the risk of S. aureus carriage in patients with diabetes may reflect association between diabetes and bacterial carriers. The aim of the study was to estimation rate of S. aureus carrier in diabetic's patients type-2 and determine antimicrobial effect of Gliotoxin on previous bacterial carriage in type-2 diabetes. The study was conducted on 450 diabetics' patients, attended the out patients clinic in Baquba Teaching Hospital, their ages ranged from 15-65 years, with mean age of 36.15, who were randomly selected, during the period from May 2016 to April 2017, patients were classified into two groups according to type of diabetes, group 1 included: 184 with type 1-diabetes, and group 2 included 266 with type 2-diabetes, 97 patients with foot ulcers. Swabs were taken from anterior nares, toe and axillae for each diabetic patient type-2, identified based on standard bacteriological methods. Using Kirby-Bauer method for detection antibacterial effect of Gliotoxin. The results showed rates of bacterial carriage in anterior nares of type-2 diabetic patients without complications were (11.4%), (4.4%), respectively for S. aureus and MRSA, in type-2 diabetes with complications were (8.6%), (2.1%) respectively for S. aureus and MRSA. The study showed the Aspergillus fumigatus Gliotoxin was effective against S. aureus and MRSA carrier in diabetics patients type-2 with foot ulcer, for S. aureus inhibition diameter was (20.50, 16.40, 12.20) mm for different concentrations of Gliotoxin, to MRSA was (8.25, 6.1, 4.20) mm. Its antibacterial effect was directly proportional with its concentration. According to the values of MIC & MBC, the results revealed that the Gliotoxin of Aspergillus fumigatus were more effective as antibacterial agent against S. aureus and MRSA. Increasing rate of S. aureus carrier in diabetic patient's type-2 which lead to a significantly increased risk of bacterial infections. Gliotoxin was effective as antibacterial agent against S. aureus in type-2 diabetes.

Keywords: Diabetes type-1, diabetes type-2, S. aureus nasal carriage, Aspergillus fumigatus, Gliotoxin (GT).

INTRODUCTION

Diabetes mellitus is a serious public health problem in worldwide [1]. Infections with diabetes are one of the leading causes of human mortality. It represents a severe complication of diabetes and the most common cause of diabetes associated hospital admissions [2]. Diabetes is a chronic infection occurs when pancreas yield in sufficiently amount of insulin and may when the body cannot efficiently use the insulin [3]. *S. aureus* are the most common bacteria isolated from ulceration of diabetes [4], chronic leg ulcers affect 1–2% of the general population and are related to increased morbidity and health costs [5]. The pathology resulting from *S. aureus* infections is of great importance due to growing resistance to antimicrobial agents [6, 7]. Multiple studies have also detected the presence of bacteria and the polymicrobial nature of chronic, non-healing wounds, and the frequency of *S. aureus* infections has to be high [8, 9]. *S. aureus* is able to produce biofilms and to express antimicrobial resistance and a variety of virulence factors such as surface proteins, endotoxins, and exoenzymes which enhances its virulence [10]. The increased carriage in patients with diabetes may reflect association between diabetes and risk factors found in the general population such as, bacterial carriers among diabetic patients [11]. The increasing association of multi-drug resistant bacteria with diabetic foot ulcers is the most problem. Initial therapy of diabetic foot infections is frequently fastidious because reliable culture data is lacking [12]. Aspergillus fumigatus is known to produce various mycotoxins including Gliotoxin, that is an alkaloid with a low molecular size, and possess number of immunosuppressive activities [13]. Antimicrobial activity cytokine release by leukocytes and T-lymphocyte-mediated cytotoxicity it is genotoxic and also causes apoptosis in macrophages. That is biologically active secondary metabolites causing serious risks for human and animal health [13].

MATERIALS AND METHOD

The study was conducted on 450 diabetic patients ascertained from a variety of sources, attended the out patients clinic in Baquba Teaching Hospital, their ages ranged from 15-65 years, during the period from May 2016 to April 2017 in Baquba city in Iraq, patients were classified into two groups according to type of diabetes, group 1 included: 184 with type 1 diabetes, and group 2: included 266 with type 2 diabetes, 97 patients with foot ulcer. Swabs were taken from anterior nares for each diabetic patient type 2, the specimens were inoculated on Blood agar and Mannitol salt agar plates by streaking methods for isolation of aerobic bacteria, incubated aerobically at 37°C for 48 hour, the isolates were identified based on standard bacteriological methods.[14]. Using Kirby-Bauer method for detection antibacterial effect of *Aspergillus fumigatus* Gliotoxin (GT) that performed and extraction
with slight modifications with 50 ml of chloroform and extracts by thin layer chromatography technique (TLC) according to [15]. **Statistical analysis:** This tool calculates the z score of the mean of a single sample.

**RESULTS AND DISCUSSION**

The study was conducted on 450 diabetic patients ascertained from a variety of sources, attended the out patients clinic in Baquba Teaching Hospital, their ages ranged from 15-65 years, during the period from May 2016 to April 2017 in Baquba city in Iraq. Patients were classified into two groups according to type of diabetes, group 1 included: 184 with type 1-diabetes, and group 2: included 266 with type 2-diabetes, 97 patients with foot ulcers. Swabs were taken from anterior nares for each patient with type 2-diabetes for detection bacterial carriers. The results as showed in table-1 explains rates of bacterial carriage in anterior nares of type 2-diabetes without complications were 21 (11.4%) and 4 (2.1%) respectively for *S. aureus*, *MRSA*, rates of bacterial carriage in type 2 diabetes with complications were 16 (8.6%), 4 (2.1%) respectively for *S. aureus*, *MRSA*, as explain in table-2. The study showed the *Aspergillus fumigatus* Gliotoxin was effective against *S. aureus* and *MRSA* carrier in diabetics patients type 2 with foot ulcer as in table-3, for *S. aureus* inhibition diameter was (20.50, 16.40, 12.20) mm for different concentrations of Gliotoxin, to *MRSA* was (8.25, 6.1, 4.20) mm.

Diabetes and it complications was chronic and non-healing due to several factors such as bacteria were the predominant pathogens in the diabetic infections especially ulcers [12], our
study revealed the high prevalence rate of bacterial carriage was observed especially in type-2 diabetes with foot ulcer. *S. aureus* was the most common bacteria of community and hospital-acquired infections that can cause morbidity and mortality, *S. aureus* nasal carriage vary between diabetic patients but increased in type-2 diabetes [13]. Increase risk of *S. aureus* and multidrug resistance bacteria especially MRSA carriage in patients with diabetes may association with many factors such as obesity, old age, in appropriate previous antibiotics treatment and prolonged hospital stay, and state for several months [15].

**CONCLUSION**

Increasing rate of *S. aureus* carrier in diabetic patient's type-2 which lead to a significantly increased risk of bacterial infections. Gliotoxin was effective as antibacterial agent against *S. aureus* in type-2 diabetes.
